# Assignment 2 - Integer Linear Programming

### Giulia Mura

5/1/2020

# Problem 1.

1. Determine the nodes that will be visited by the BB algorithm and for each of them get the upper and lower limit deduced by the algorithm in the execution.

```
I nodi che saranno visitati dall'algoritmo Branch-And-Bound sono: P_0, P_1, P_2, P_7, P_9, P_{11}, P_{12}. Per il nodo P_0 abbiamo UB=16.5 e LB=9. Per il nodo P_1 abbiamo UB=16.2 e LB=12.2. Per il nodo P_2 abbiamo UB=9 e LB=9. Per il nodo P_7 abbiamo UB=16 e LB=14. Per il nodo P_9 abbiamo UB=16 e LB=14. Per il nodo P_{11} abbiamo UB=14 e LB=14. Per il nodo P_{12} abbiamo UB=13.8 e LB=9. Infatti, secondo l'albero rappresentato la soluzione ottimale intera è pari a 14 e si trova con il nodo P_{11}.
```

2. Solve the problem with an ILP solver and check the value of the objective function matches the one found at point 1.

```
\begin{aligned} & max: 9x_1 + 5x_2 + 6x_3 + 4x_4\\ & s.t.\\ & 6x_1 + 3x_2 + 5x_3 + 2x_4 \leq \ 10\\ & x_3 + x_4 \leq \ 1\\ & -x_1 + x_3 \leq \ 0\\ & -x_2 + x_4 \leq \ 0\\ & x_1, x_2, x_3, x_4 \in \{0, 1\} \end{aligned}
```

### Creo il modello

```
model = make.lp(0,4, verbose = "full")
name.lp(model, 'Max')
lp.control(model, sense = "max")
```

#### Creo la funzione obiettivo

```
set.objfn(model, obj = c(9, 5, 6, 4))
```

### Inserisco le constraints

### Risolvo il modello

```
solve(model)
## Model name: 'Max' - run #1

## Problem 2.

SunNet is a residential Internet Service Provider (ISP) in the central Florida area. Presently, the company operates one centralized facility that all of its clients call into for Internet access.

To improve service, the company is planning to open three satellite offices in the cities of Pine Hills, Eustis, and Sanford. The company has identified five different regions to be serviced by these three offices. The following table summarizes the number of customers in each region, the service capacity at each office, and the monthly average cost per customer for providing the service to each region from each office. Table entries of "n.a." indicate infeasible region-to-service center combinations.

SunNet would like to determine how many customers from each region to assign to each service center to minimize the total cost.

### 1. Draw a network flow model to represent this problem.

```
knitr::include_graphics("/Users/giulia/NetFlow.png")
```

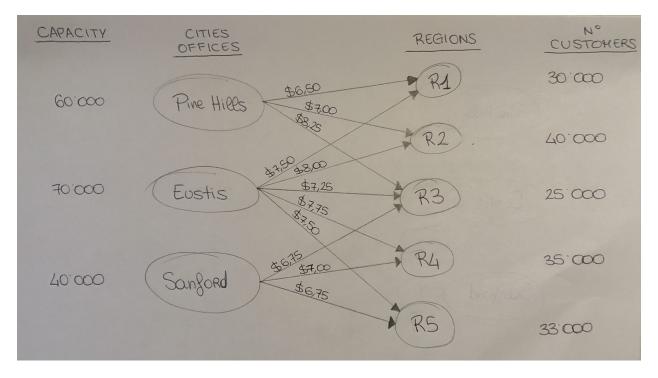

Figure 1: Network Flow

## 2. Implement your model and solve it.

### The decision variables

```
x_1 = \text{service from Pine Hills to region 1}
x_2 = \text{service from Pine Hills to region 2}
x_3 = \text{service from Pine Hills to region 3}
x_4 = \text{service from Eustis to region 1}
x_5 = \text{service from Eustis to region 2}
x_6 = \text{service from Eustis to region 3}
x_7 = \text{service from Eustis to region 4}
x_8 = \text{service from Eustis to region 5}
x_9 = \text{service from Sanford to region 3}
x_{10} = \text{service from Sanford to region 4}
```

### The objective function

```
min: 6.50x_1 + 7x_2 + 8.25x_3 + 7.50x_4 + 8x_5 + 7.25x_6 + 7.75x_7 + 7.50x_8 + 6.75x_9 + 7x_{10} + 6.75x_{11}
```

# The constraints

```
Costo massimo PineHills: x_1+x_2+x_3 \leq 60000 Costo massimo Eustis: x_4+x_5+x_6+x_7+x_8 \leq 70000 Costo massimo Sanford: x_9+x_{10}+x_{11} \leq 40000 Consumatori per la regione 1: x_1+x_4=30000 Consumatori per la regione 2: x_2+x_5=40000 Consumatori per la regione 3: x_3+x_6+x_9=25000 Consumatori per la regione 4: x_7+x_{10}=35000 Consumatori per la regione 5: x_8+x_{11}=33000
```

```
##
